

FISSIDENS SUBG. PACHYFISSIDENS

Fissidens subg. *Pachyfissidens* (Müll.Hal.) Kindb., *Gen. Eur. North Amer. Bryin.* 2: 165 (1897)

Fissidens sect. *Pachyfissidens* Müll.Hal., *Syn. Musc. Frond.* 1: 45 (1848); *Pachyfissidens* (Müll.Hal.) Limpr., *Laubm. Deutschl.* 4(1): 454 (1887).

Type: *F. grandifrons* Brid.

Aquatic plants, rather rigid. Stems lacking a central strand. Leaves 2 or more cells thick near the costa, unistratose towards the margin. Costa with 2 stereid bands. Capsules lateral, lacking stomata. Peristome a form of *taxifolium*-type or *zippelianus*-type.

One species is known from southern Australia.

Autoicous. Plants rigid, erect, blackish green, 10–20 mm tall. Leaves erectopatent when wet or dry, imbricate, linear, acute; upper leaves c. 2 mm long. Costa yellow or reddish, rather strong, subpercurrent. Margin minutely crenulate near the apex. Laminal cells ±round, irregular, markedly thick-walled, 12–14 µm diam., smooth or slightly convex, bistratose to multistratose in the dorsal and apical laminae, except for a broad unistratose border; cells in the marginal row 6–8 µm diam.

Setae short, terminal on an axillary branch. Capsules small, obconical. Peristome teeth 50–70 µm or 60–90 µm wide at the base; ornamentation similar to *zippelianus*-type, with trabeculae in lower part of the teeth double and forked, with oblique rilets distally and ±strongly papillose.

Occurs in southern Vic. and Tas. Also in northern New Zealand and the Auckland Islands, and recently reported from Nepal (Pradhan & Joshi, 2006).
