

RADULINA

Helen P. Ramsay¹

Radulina W.R.Buck & B.C.Tan, *Acta Bryolichenol. Asiatica* 1: 9 ('1989') [1990]; derived from the Latin *radula* (a small scraper), in reference to the seriate papillae on laminal cells.

Hypnum sect. *Sigmatella* subsect. *Thelidium* Müll.Hal., *Linnaea* 39: 466 (1875); *Trichosteleum* sect. *Thelidium* (Müll.Hal.) A.Jaeger, *Ber. Thätigk. St. Gallischen Naturwiss. Ges.* 1876–77: 419 (1878), *non Thelidium* A.Massal. (Ascomycota, Verrucariales).

Lecto: *Hypnum pickeringii* Sull. [= *Radulina borbonica* (Bél.) W.R.Buck]

Autoicous. Plants small to medium in mostly thin dull and green to golden mats. Stems creeping, freely but irregularly branched; branches often ascending and falcate-cuspidate. Pseudoparaphyllia foliose. Leaves strongly falcate-secund, scarcely altered when dry, lanceolate to ovate-lanceolate, gradually long-acuminate, concave; margins plane, serrulate above, serrulate to entire below; costa usually absent, occasionally short and double. Laminal cells elongate, hexagonal to linear, firm- to thick-walled, ±porose, pluripapillose, the unbranched papillae uniseriate to biseriate over the lumina; alar region differentiated; basal cells larger, inflated; outermost cells thin-walled, others yellow, thick-walled, in a single row across the insertion; supra-alar cells quadrate, in a single row.

Calyptra cucullate, naked. Seta slender, elongate, reddish, tuberculate just below the capsule, smooth below. Capsule inclined to horizontal, arcuate, short-cylindrical; exothecial cells short-rectangular, strongly collenchymatous; annulus lacking; operculum obliquely long-rostrate. Peristome double; exostome teeth and endostome segments 16, similar in length; cilium 1. Spores medium-sized, finely papillose. Chromosome numbers not known.

Buck & Tan (1990) recognised four species of *Radulina*, including *R. hamata*. Subsequently, Buck (1993) added a fifth species, *R. borbonica*. Tan *et al.* (2005) suggested that the genus was confined to western Melanesia, especially Papua New Guinea, while Ramsay *et al.* (2004) reported *R. hamata* from Australia. A more recent revision by O'Shea (2006) examined large numbers of collections, including types, and has concluded that the genus comprises four species and an additional variety. His assertion that *R. hamata* is conspecific with *R. borbonica* is accepted here. Thus, the Palaeotropical *Radulina* occurs in tropical Africa and islands in the western Indian Ocean, as well as India, SE Asia, Malesia, Japan and the Pacific islands. Only one species, the widespread *R. borbonica*, is known from northern Australia

Both *Radulina* and *Trichosteleum* have pluripapillose laminal cells. However, the former can be characterised by its narrowly ovate-lanceolate falcate-secund leaves with inflated basal alar cells and setae that are distally verrucose. Although *Radulina* can resemble *Acroporium* in having cuspidate branch apices and concave leaves with thick-walled laminal cells, it is distinguished by the pluripapillose laminal cells and alar cells that do not curve in towards the insertion.

Plants variable, forming dense intricate tufts or mats, pale or lurid green, dull to slightly glossy. Stems irregularly pinnate; branches decumbent or ascending, 2–3 mm long, usually hooked at the tips. Leaves crowded, gradually lanceolate-acuminate from a concave expanded ovate base, 1.0–2.2 mm long, c. 0.5 mm wide, often smaller, ecostate; margins erect, sharply serrate distally. Laminal cells linear to narrowly elliptic, 30–50 µm long, c. 5 µm wide, with a row of papillae over the lumina; alar region with a basal row of 2 or 3 large inflated hyaline cells.

Perichaetia on stems; perichaetal leaves abruptly long-acuminate, sharply serrate. Seta 10–15 mm long. Capsule small, c. 0.5 mm long, ovoid, horizontal-pendulous; operculum with a short rostrum. Peristome double; exostome teeth 16, narrowly furrowed on the outer surface, cross-striolate below, coarsely papillose above, trabeculate on the abaxial surface; endostome with a high basal membrane; segments keeled, perforate, shorter than the teeth; cilium 1, narrow, neither nodulose nor appendiculate.

Widespread from Malesia through the Pacific to the Hawaiian Islands; also in tropical Africa, India, Indian Ocean islands, SE Asia, China, Japan, Papua New Guinea and Australia (N.T. and north-eastern Qld). Occurs in dry coastal and montane rainforest, on trees and on rotting logs on river flats and slopes.

Radulina borbonica is characterised by the slender, strongly falcate, serrulate leaves with pluripapillose laminal cells. The pluripapillose cells give fresh specimens a dull green appearance.
